C Basics

Discussion 2: January 25, 2021

1 Pre-Check

This section is designed as a conceptual check for you to determine if you conceptually understand and have any misconceptions about this topic. Please answer true/false to the following questions, and include an explanation:

- 1.1 True or False: C is a pass-by-value language.
- 1.2 What is a pointer? What does it have in common to an array variable?
- 1.3 If you try to dereference a variable that is not a pointer, what will happen? What about when you free one?
- 1.4 When should you use the heap over the stack? Do they grow?

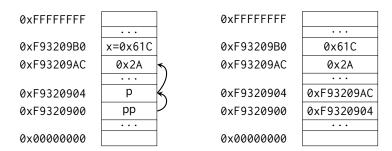

2 C

C is syntactically similar to Java, but there are a few key differences:

- 1. C is function-oriented, not object-oriented; there are no objects.
- 2. C does not automatically handle memory for you.
 - Stack memory, or things that are not manually allocated: data is garbage immediately after the function in which it was defined returns.
 - Heap memory, or *things allocated with* malloc, calloc, *or* realloc: data is freed only when the programmer explicitly frees it!
 - There are two other sections of memory that we learn about in this course, static and code, but we'll get to those later.
 - In any case, allocated memory always holds garbage until it is initialized!
- 3. C uses pointers explicitly. If p is a pointer, then *p tells us to use the value that p points to, rather than the value of p, and &x gives the address of x rather than the value of x.

On the left is the memory represented as a box-and-pointer diagram.

On the right, we see how the memory is really represented in the computer.

Let's assume that int* p is located at 0xF9320904 and int x is located at 0xF93209B0. As we can observe:

- *p evaluates to 0x2A (42_{10}) .
- p evaluates to 0xF93209AC.
- \bullet x evaluates to 0x61C.
- &x evaluates to 0xF93209B0.

Let's say we have an **int** **pp that is located at 0xF9320900.

- 2.1 What does pp evaluate to? How about *pp? What about **pp?
- 2.2 The following functions are syntactically-correct C, but written in an incomprehensible style. Describe the behavior of each function in plain English.
 - (a) Recall that the ternary operator evaluates the condition before the ? and returns the value before the colon (:) if true, or the value after it if false.

```
int foo(int *arr, size_t n) {
return n ? arr[0] + foo(arr + 1, n - 1) : 0;
}
```

(b) Recall that the negation operator, !, returns 0 if the value is non-zero, and 1 if the value is 0. The ~ operator performs a bitwise not (NOT) operation.

```
int bar(int *arr, size_t n) {
    int sum = 0, i;
    for (i = n; i > 0; i--)
        sum += !arr[i - 1];
    return ~sum + 1;
}
```

(c) Recall that $\hat{}$ is the $bitwise\ exclusive-or$ (XOR) operator.

```
void baz(int x, int y) {
      x = x ^ y;
```

(d) (Bonus: How do you write the bitwise exclusive-nor (XNOR) operator in C?)

3 Programming with Pointers

- [3.1] Implement the following functions so that they work as described.
 - (a) Swap the value of two ints. Remain swapped after returning from this function. void swap(

(b) Return the number of bytes in a string. Do not use strlen.

```
int mystrlen(
```

- 3.2 The following functions may contain logic or syntax errors. Find and correct them.
 - (a) Returns the sum of all the elements in summands.

```
int sum(int* summands) {
    int sum = 0;
    for (int i = 0; i < sizeof(summands); i++)
        sum += *(summands + i);
    return sum;
}</pre>
```

(b) Increments all of the letters in the string which is stored at the front of an array of arbitrary length, $n \ge strlen(string)$. Does not modify any other parts of the array's memory.

```
void increment(char* string, int n) {
for (int i = 0; i < n; i++)</pre>
```

```
3 *(string + i)++;
4 }
```

(c) Copies the string src to dst.

```
void copy(char* src, char* dst) {
while (*dst++ = *src++);
}
```

(d) Overwrites an input string src with "61C is awesome!" if there's room. Does nothing if there is not. Assume that length correctly represents the length of src.

4 Memory Management

- 4.1 For each part, choose one or more of the following memory segments where the data could be located: **code**, **static**, **heap**, **stack**.
 - (a) Static variables
 - (b) Local variables
 - (c) Global variables
 - (d) Constants
 - (e) Machine Instructions
 - (f) Result of malloc
 - (g) String Literals

- 4.2 Write the code necessary to allocate memory on the heap in the following scenarios
 - (a) An array arr of k integers
 - (b) A string str containing p characters
 - (c) An $n \times m$ matrix mat of integers initialized to zero.
- 4.3 What's the main issue with the code snippet seen here? (Hint: gets() is a function that reads in user input and stores it in the array given in the argument.)

```
char* foo() {
char buffer[64];
gets(buffer);

char* important_stuff = (char*) malloc(11 * sizeof(char));

int i;
for (i = 0; i < 10; i++) important_stuff[i] = buffer[i];
important_stuff[i] = '\0';
return important_stuff;
}</pre>
```

Suppose we've defined a linked list **struct** as follows. Assume *lst points to the first element of the list, or is NULL if the list is empty.

```
struct ll_node {
    int first;
    struct ll_node* rest;
}
```

4.4 Implement prepend, which adds one new value to the front of the linked list. Hint: why use ll_node ** lst instead of ll_node*lst?

```
void prepend(struct ll_node** lst, int value)
```

[4.5] Implement free_11, which frees all the memory consumed by the linked list.

```
void free_ll(struct ll_node** lst)
```
